1 INTRODUCTION

Numerical methods of solving partial differential equations (PDE) have demonstrate far better performance than many other methods such as finite difference methods (FDM) [**<empty citation>**], finite element methods (FEM) [**<empty citation>**], Lattice Boltzmann Method (LBM) [**<empty citation>**] and Monte Carlo Method (MC) [**<empty citation>**]. In recent years, researchers in the field of deep learning have mainly focused on how to develop more powerful system architectures and learning methods such as convolution neural networks (CNNs) [**<empty citation>**], Transformers [**<empty citation>**] and Perceivers [**<empty citation>**]. In addition, more researchers have tried to develop more powerful models specifically for numerical simulations. Despite of the relentless progress, modeling and predicting the evolution of nonlinear multiscale systems which has inhomogeneous cascades-scales by using classical analytical or computational tools inevitably encounters severe challenges and comes with prohibitive cost and multiple sources of uncertainty.

This project focuses on the promotions on performance gained from the parallel compute systems, in general, the FDMs and Neural Networks (NNs) are evaluated. Moreover, it prompted series Message Passing and Shared

2 RELATED WORK

To gain well quality solution of various types of PDEs is prohibitive and notoriously challanging. The number of methods available to determine canonical PDEs is limited as well, includes separation of variables, superposition, product solution methods, Fourier transforms, Laplace transforms and perturbation methods, among a few others. Even though there methods are exclusively well-performed on constrained conditions, such as regular shaped geometry domain, constant coefficients, well-symmetric conditions and many others. These limits strongly constrained the range of applicability of numerical techniques for solving PDEs, rendering them nearly irrelevant for solving problems pratically.

General, the methods of determining numerical solutions of PDEs can be broadly classified into two types: deterministic and stochastic. The mostly widely used stochastic method for solving PDEs is Monte Carlo Method [Monte Carlo Method] which is a popular method in solving PDEs in higher dimension space with notable complexity.

2.1 Finite Difference Method

The Finite Difference Method(FDM) is based on the numerical approximation method in calculus of finite differences. The motivation is quite straightforward which is approximating solutions by finding values satisfied PDEs on a set of presctibed interconnected points within the domain of it. Those points are which referd as nodes, and the set of nodes are so called as a grid of mesh. A notable way to approximate derivatives are using Taylor Series expansions. Taking 2 dimension Possion Equation as instance, assuming the investigated value as, φ ,

$$\frac{\partial^2 \varphi}{\partial x^2} + \frac{\partial^2 \varphi}{\partial y^2} = f(x, y) \quad (1)$$

The total amount of nodes is denoted with $N = 15$, which gives the numerical equation which governing equation 1 shown in equation 2 and nodes layout as shown in the figure 1

$$\frac{\partial^2 \varphi_i}{\partial x_i^2} + \frac{\partial^2 \varphi_i}{\partial y_i^2} = f(x_i, y_i) = f_i, \quad i = 1, 2, \dots, 15 \quad (2)$$

In this case, we only need to find the value of internal nodes which i is ranging from 1 to 10. Next is aiming to solve this linder system 2.

2.2 Physics Informed Neural Networks

With the explosive growth of available data and computing resources, recent advances in machine learning and data analytics have yielded good results across science discipline, including Convolutional Neural Networks (CNNs) [CNN] for image recognition, Generative Pre-trained Transformer (GPT) [GPT] for natural language processing and Physics Informed Neural Networks (PINNs) [PINN] for handling science problems with high complexity. PINNs is a type of machine learning model makes full use of the benefits from Auto-differentiation (AD) [AD] which led to the emergence of a subject called Matrix Calculus [Matrix_Calculus]. Considering the parametrized and nonlinear PDEs of the general form [E.q. 3] of function $u(t, x)$

$$u_t + \mathcal{N}[u; \lambda] = 0 \quad (3)$$

The $\mathcal{N}[\cdot; \lambda]$ is a nonlinear operator which parametrized by λ . This setup includes common PDEs problems like heat equation, and black-stokz equation and others. In this case, we setup a neural network $NN[t, x; \theta]$ which has trainable weights θ and takes t and x as inputs, outputs with the predicting value $\hat{u}(t, x)$. In the training process, the next step is

Fig. 1. The Schematic Representa of of a 2D Computational Domain and Grid. The nodes are used for the FDM by solid circles. Nodes 11 – 15 denote boundary nodes, while nodes 1 – 10 denote internal nodes.

calculating the necessary derivatives of u with the respect to t and x . The value of loss function is a combination of the metrics of how well does these predictions fit the given conditions and fit the natural law [Fig. 2].

Fig. 2. The Schematic Representa of a structure of PINN.

2.3 Finite Difference Time Domain Method

As described previously in the section 2.1, FDM could solve the PDEs in its original form where Finite Element and Finite Volume Methods gained results by solving modified form such as an integral form of the governing equation. Though the latter methods are commonly get better results or less computational hungry, the FDM has many descendants, for instance the Finite Difference Time Domain Method (FDTD) where it still finds prolific usage are computational heat equation and computational electromagnetics (Maxwell's equations [Maxwell_equations]). Assuming the operator

$\mathcal{N}[\cdot; \lambda]$ is set to ∇ where it makes E.q. 3 become to heat equation 4.

$$\frac{\partial u}{\partial t} - \lambda \left(\frac{\partial^2 u}{\partial x^2} + \frac{\partial^2 u}{\partial y^2} \right) = 0 \quad (4)$$

Using the key idea of FDM, assuming the step size in spatio-time space are Δx , Δy and Δt , we could have a series equations which have form [E.q. 5].

$$\frac{u_{i,j}^{n+1} - u_{i,j}^n}{\Delta t} = \lambda \left(\frac{u_{i+1,j}^n - 2u_{i,j}^n + u_{i-1,j}^n}{\Delta x^2} + \frac{u_{i,j+1}^n - 2u_{i,j}^n + u_{i,j-1}^n}{\Delta y^2} \right) \quad (5)$$

when the time step size satisfies the Couran, Friedrichs, and Lewy condition (CFL[CFL_limitation]). We could get the strong results by iterating the equation 5, or more specifically using equation 6 to get the value u of next time stamp $n + 1$ on nodes i, j .

$$u_{i,j}^{n+1} = u_{i,j}^n + \frac{\lambda \Delta t}{\Delta x^2} (u_{i+1,j}^n - 2u_{i,j}^n + u_{i-1,j}^n) + \frac{\lambda \Delta t}{\Delta y^2} (u_{i,j+1}^n - 2u_{i,j}^n + u_{i,j-1}^n) \quad (6)$$

also shown in the figure 3.

Fig. 3. The Schematic Representa the computational spatio-time domain of FDTD methods.

3 PROBLEM SETUPS

Due to the inherent limitations of current computing systems, obtaining sufficiently precise solutions is both computationally expensive and time-consuming. These challenges arise from the constraints imposed by the clock speed of computing units, as described by Moore's Law [Moore_Law], as well as the relatively low communication speeds between these units. While modern numerical methods have advanced to a level where they can produce satisfactory results within acceptable time frames across many research domains, the increasing scale of problems we aim to solve has driven the search for more cost-effective approaches. This has led to a growing interest in neural networks as a promising alternative.

In this project, I aim to evaluate the performance of the Finite-Difference Time-Domain (FDTD) method and the Physics-Informed Neural Network (PINN) model within parallelized computing environments by find the steady-state solution of PDEs. These two methodologies broadly represent the current approaches to handling PDEs, specifically CPU-based parallelization and GPU-based parallelization.

3.1 General Form

Starting with the general form of the PDEs, rather than the specific equations, is because different equations give perform differently on the same compute system. To this end, consider the previously discussed form of PDEs shown in equation 3 which parametrized by number λ and an operator $\mathcal{N}[\cdot; \lambda]$. Moreover, we assume the variable x is a 2D or 3D spatio vector which is written in $\vec{x} \in \mathbb{R}^d$, $d = 2, 3$. The domain of this PDE system is considered between 0 and 1, where is denoted with $\Omega = [0, 1]^d$, $d = 2, 3$. To these setups, we have the general form of the PDEs we are going to investigated, shown in equations 7

$$\begin{aligned} \frac{\partial u}{\partial t}(t, \vec{x}) + \mathcal{N}[u(t, \vec{x}); \lambda] &= 0, & \vec{x} \in \Omega, t \in [0, +\infty) \\ u(0, \vec{x}) &= \varphi(\vec{x}), & \vec{x} \in \Omega \\ u(t, \vec{x}) &= g(t, \vec{x}), & \vec{x} \in \overline{\Omega}, t \in [0, +\infty) \end{aligned} \quad (7)$$

The boundary condition shown in E.q. 7 is Dirichlet Condition known as first type boundary condition, where as the second type boundary condition (Von Neumann) [E.q. 8] gives the other form of $u(t, \vec{x})$ at the boundary $\overline{\Omega}$.

$$\frac{\partial u}{\partial \vec{x}} = g(t, \vec{x}), \quad \vec{x} \in \overline{\Omega}, \quad t \in [0, +\infty) \quad (8)$$

3.2 Computational Topology

The computational topology is critically important when we are programming parallel PDEs solver softwares. Put the strongly speed-dependent data into the slow memory could make entire program slower. The cluster we are using for this project is Callan [Callan_TCD] which has 2 CPUs per compute node, and each CPU has 32 cores with single thread. The Non-Uniform Memory Access (NUMA) nodes are layout as following Accessing the other NUMA node's memory reduces the bandwidth and also the latency, though the bandwidth is commonly high enough, the latency can increase by 30% to 400% [NUMA_Latency_TCD]. This latency becomes dangerous when writing shared memory parallel programmes.

Fig. 4. NUMA topology of single node on Callan

4 METHODOLOGY

For solving the PDEs, we need to begin with discretizing the objects or the region we are going to evaluate via matrices. Without considering more detail, the naive way for these transforming processes is to simply using the coordinates in d dimension spaces and the values of function at the points to simplify the objects. One of the famous numerical methods based on such methodology is called Finite Difference Method (FDM [**FDM**]), which is a fine way to investigate objects with regular shapes such as Cube.

Fig. 5. Figure Shows the FDM idea, If NEED

The other type of methods are aiming to solve systems on irregular shapes, such as simulating the aerodynamics effects of a jet. The methods, Finite Elements Methods (FEM [**FEM**]), are start with deviding the objects into numbers of elements, typically quadrilateral in 2D spaces and tetrahedron in 3D spaces.
