1 INTRODUCTION

Numerical methods of solving partial differential equations (PDE) have demonstrate far better performance than many other methods such as finite difference methods (FDM) [<empty citation>], finite element methods (FEM) [<empty citation>], Lattice Boltzmann Method (LBM) [<empty citation>] and Monte Carlo Method (MC) [<empty citation>]. In recent years, researchers in the field of deep learning have mainly focused on how to develop more powerful system architectures and learning methods such as convolution neural networks (CNNs) [<empty citation>], Transformers [<empty citation>] and Perceivers [<empty citation>] . In addition, more researchers have tried to develop more powerful models specifically for numerical simulations. Despite of the relentless progress, modeling and predicting the evolution of nonlinear multiscale systems which has inhomogeneous cascades-scales by using classical analytical or computational tools inevitably encounts severe challanges and comes with prohibitive cost and multiple sources of uncertainty.

This project focuses on the promotions on performance gained from the parallel compute systems, in general, the FDMs and Neural Networks (NNs) are evaluated. Moreover, it prompted series Message Passing and Shared Memory hybrid parallel strategies using Message Passing Interface (MPI) [7] and Open Multi-processing (OpenMP) [3].

2 RELATED WORK

 To gain well quality solution of various types of PDEs is prohibitive and notoriously challenging. The number of methods available to determine canonical PDEs is limited as well, includes separation of variables, superposition, product solution methods, Fourier transforms, Laplace transforms and perturbation methods, among a few others. Even though there methods are exclusively well-performed on constrained conditions, such as regular shaped geometry domain, constant coefficients, well-symmetric conditions and many others. These limits strongly constrained the range of applicability of numerical techniques for solving PDEs, rendering them nearly irrelevant for solving problems practically.

General, the methods of determining numerical solutions of PDEs can be broadly classified into two types: deterministic and stochastic. The mostly widely used stochastic method for solving PDEs is Monte Carlo Method [Monte Carlo Method] which is a popular method in solving PDEs in higher dimension space with notable complexity.

2.1 Finite Difference Method

The Finite Difference Method(FDM) is based on the numerical approximation method in calculus of finite differences. The motivation is quiet straightforward which is approximating solutions by finding values satisfied PDEs on a set of prescribed interconnected points within the domain of it. Those points are which referred as nodes, and the set of nodes are so called as a grid of mesh. A notable way to approximate derivatives are using Taylor Series expansions. Taking 2 dimension Possion Equation as instance, assuming the investigated value as, φ ,

$$\frac{\partial^2 \varphi}{\partial x^2} + \frac{\partial^2 \varphi}{\partial y^2} = f(x, y) \tag{1}$$

The total amount of nodes is denoted with N = 15, which gives the numerical equation which governing equation 1 shown in equation 2 and nodes layout as shown in the figure 1

$$\frac{\partial^2 \varphi_i}{\partial x_i^2} + \frac{\partial^2 \varphi_i}{\partial y_i^2} = f(x_i, y_i) = f_i, \quad i = 1, 2, \dots, 15$$
 (2)

In this case, we only need to find the value of internal nodes which i is ranging from 1 to 10. Next is aimming to solve

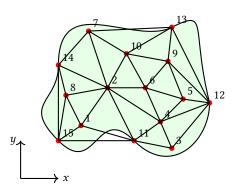

Fig. 1. The Schematic Representa of of a 2D Computiational Domain and Grid. The nodes are used for the FDM by solid circles. Nodes 11 - 15 denote boundary nodes, while nodes 1 - 10 denote internal nodes.

this linder system 2.

2.2 Physics Informed Neural Networks

With the explosive growth of avaliable data and computing resouces, recent advances in machine learning and data analytics have yieled good results across science discipline, including Convolutional Neural Networks (CNNs) [15] for image recognition, Generative Pre-trained Transformer (GPT) [19] for natual language processing and Physics Informed Neural Networks (PINNs) [14] for handling science problems with high complexity. PINNs is a type of machine learning model makes full use of the benefits from Auto-differentiation (AD) [2] which led to the emergence of a subject called Matrix Calculus [17]. Considering the parametrized and nonlinear PDEs of the general form [E.q. 3] of function u(t,x)

$$u_t + \mathcal{N}\left[u;\lambda\right] = 0\tag{3}$$

The $\mathcal{N}[\cdot;\lambda]$ is a nonlinear operator which parametrized by λ . This setup includes common PDEs problems like heat equation, and black-stokz equation and others. In this case, we setup a neural network $NN[t,x;\theta]$ which has trainable weights θ and takes t and x as inputs, outputs with the predicting value $\hat{u}(t,x)$. In the training process, the next step is calculating the necessary derivatives of u with the respect to t and x. The value of loss function is a combination of the metrics of how well does these predictions fit the given conditions and fit the natural law [Fig. 2].

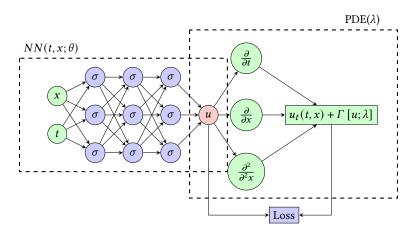

Fig. 2. The Schematic Representation of a structure of PINN, a FCN with 4 layers (3 hidden layers)

2.3 Finite Difference Time Domain Method

As described previously in the section 2.1, FDM could solve the PDEs in its original form where Finite Element and Finite Volume Methods gained results by solving modified form such as an integral form of the governing equation. Though the latter methods are commonly get better results or less computational hungery, the FDM has many descendants, for instance the Finite Difference Time Domain Method (FDTD) where it still finds prolific usage are computational heat equation and computational electromagnetics (Maxwell's equations). Assuming the operator $\mathcal{N}[\cdot;\lambda]$ is set to ∇ where it makes E.q. 3 become to heat equation 4.

$$\frac{\partial u}{\partial t} - \lambda \left(\frac{\partial^2 u}{\partial x^2} + \frac{\partial^2 u}{\partial y^2} \right) = 0 \tag{4}$$

Using the key idea of FDM, assuming the step size in spatio-time space are Δx , Δy and Δt , we could have a series equations which have form [E.q. 5].

$$\frac{u_{i,j}^{n+1} - u_{i,j}^n}{\Delta t} = \lambda \left(\frac{u_{i+1,j}^n - 2u_{i,j}^n + u_{i-1,j}^n}{\Delta x^2} + \frac{u_{i,j+1}^n - 2u_{i,j}^n + u_{i,j+1}^n}{\Delta y^2} \right)$$
 (5)

when the time step size satisfies the Couran, Friedrichs, and Lewy condition (CFL[8]). We could get the strong results by iterating the equation 5, or more specifically using equation 6 to get the value u of next time stamp n + 1 on nodes i, j.

$$u_{i,j}^{n+1} = u_{i,j}^{n} + \frac{\lambda \Delta t}{\Delta x^{2}} \left(u_{i+1,j}^{n} - 2u_{i,j}^{n} + u_{i-1,j}^{n} \right) + \frac{\lambda \Delta t}{\Delta y^{2}} \left(u_{i,j+1}^{n} - 2u_{i,j}^{n} + u_{i,j+1}^{n} \right)$$
(6)

also shown in the figure 3.

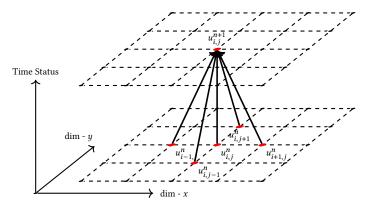

Fig. 3. The Schematic Representation the computational spatio-temporal domain of FDTD methods.

2.4 Scalability

High performance computing which also called parallel computing is solving large scale problems using Clusters, with a number of compute nodes and many CPUs. Parallel computing is many CPUs, thousands of CPUs in most case, are simultaneously processing the data and producing the exceptional results, which significantly reduce the time consumption totally. In this scenario, scaling test is a widely used to investigate the ability of hardware and programs to deliver more computational power when the amount of compute resources increase.

2.4.1 Amdalh's Law and Strong Scaling. The Amdalh's law for speedup is

Theorem 2.1. Let f_s and f_p be the fraction of time spend on purely sequential tasks and that can be parallelized, then the Amdalh's formula [1] of final speedup is

$$S_N = \frac{1}{f_s + \frac{f_p}{N}} \tag{7}$$

and it states that for a fixed problem, the upper limits of speedup is restricted by the fraction of sequential parts, where the limits is $\lim_{N\to+\infty} S_N = 1/f_s$, which is called the strong scaling.

2.4.2 Gustafsson-Barsis' Law. The Gaustafsson-Barsis' law for speedup is

Theorem 2.2. Let f_s and f_p be the fraction of time spend on purely sequential tasks and that can be parallelized, then the Gaustafsson-Barsis' formula [11] of the final speedup is

$$S_N = f_S + N f_D \tag{8}$$

With Gaustafsson-Barsis's law, the scaled speedup increases linearly with the number of processes, and there is no upper limits for the scaled speedup, which is called weak scaling.

The weak scaling tests of an high performance program runing on cluster is necessary for researching the inner relationships between the number of CPUs and the scale of problems. In order to get better weak scaling performance, the fraction of synchronization among processes and the cost of communications plays a minor role when the number of resources increase. In the meanwhile, unlike the strong scaling test, the iterations takes for converging on different problem sizes are various as well. Thus, the weak scaling is more effective if it only consider the scaling for single iteration, where the speedup on N CPUs has formula follows

$$S_N = N \frac{T_1 C_N}{C_1 T_N} \tag{9}$$

where T_N and C_N denote with the time and epochs that the solver takes for converging on N CPUs.

3 PROBLEM SETUPS

Due to the inherent limitations of current computing systems, obtaining sufficiently precise solutions is both computationally expensive and time-consuming. These challenges arise from the constraints imposed by the clock speed of computing units, as described by Moore's Law [10], as well as the relatively low communication speeds between these units. While modern numerical methods have advanced to a level where they can produce satisfactory results within acceptable time frames across many research domains, the increasing scale of problems we aim to solve has driven the search for more cost-effective approaches. This has led to a growing interest in neural networks as a promising alternative.

In this project, I aim to evaluate the performance of the Finite-Difference Time-Domain (FDTD) method and the Physics-Informed Neural Network (PINN) model within parallelized computing environments by find the steady-state solution of PDEs. These two methodologies broadly represent the current approaches to handling PDEs, specifically CPU-based parallelization and GPU-based parallelization.

3.1 General Form

Starting with the general form of the PDEs, rather than the specific euqations, is because different equations give perform differently on the same compute system. To this end, consider the previously discussed form of PDEs shown in equation 3 which parametrized by number λ and an operator $\mathcal{N}[\cdot; \lambda]$. Moreover, we assume the variable x is a 2D or 3D spatio vector which is written in $\vec{x} \in \mathbb{R}^d$, d = 2, 3.

$$\frac{\partial u}{\partial t}(t,\vec{x}) + \mathcal{N}\left[u(t,\vec{x});\lambda\right] = 0, \qquad \vec{x} \in \Omega, t \in [0, +\infty)$$

$$u(0,\vec{x}) = \varphi(\vec{x}), \qquad \vec{x} \in \Omega$$

$$u(t,\vec{x}) = g(t,\vec{x}), \qquad \vec{x} \in \overline{\Omega}, t \in [0, +\infty)$$
(10)

The domain of this PDE system is considered between 0 and 1, where is denoted with $\Omega = [0,1]^d$, d=2,3. To these setups, we have the general form of the PDEs we are going to investigated, shown in equations 10 The boundary condition shown in E.q. 10 is Dirichlet Condition known as first type boundary condition, where as the second type boundary condition (Von Neuman) [E.q. 11] gives the other form of $u(t, \vec{x})$ at the boundary $\overline{\Omega}$.

$$\frac{\partial u}{\partial \vec{x}} = g(t, \vec{x}), \ \vec{x} \in \overline{\Omega}, \ t \in [0, +\infty)$$
(11)

3.2 Specific Form

With general form proposed in section 3.1[E.q. 10], I specify a particular form of this heat problem to help us to have better understand the quality of our solutions and programs. In 2 dimension space, the domain $\Omega = [0, 1]^2 \in \mathbb{R}^2$ and its

boundary denoted with $\overline{\Omega}$, the initial condition $\varphi(x,y)=0$. such problem has the certain form below

$$\frac{\partial u}{\partial t} = \alpha \left(\frac{\partial u^2}{\partial^2 x} + \frac{\partial u^2}{\partial^2 y} \right)$$
 $(x, y) \in \Omega, \ t \in [0, +\infty)$
$$u(0, x, y) = \varphi(x, y) = 0$$
 $(x, y) \in \Omega$ (12)

$$u(t, x, y) = g(x, y) = \begin{cases} y, & x = 0, y \in (0, 1) \\ 1, & x = 1, y \in (0, 1) \\ x, & y = 0, x \in (0, 1) \\ 1, & y = 1, x \in (0, 1) \end{cases}$$

$$t \in [0, +\infty)$$

With given format, and $\alpha = 1$, we have the analytical solution of this equations, where is

$$u(t, x, y) = x + y - xy, (x, y) \in \Omega, t \in [0, +\infty)$$
 (13)

In 3 dimension space, similarly, with identical initial condition set up to 0, coefficient $\alpha = 1$, the boundaries are

$$u(t, x, y, z) = g(x, y, z) = \begin{cases} y + z - 2yz, & x = 0, \\ 1 - y - z + 2yz, & x = 1, \\ x + z - 2xz, & y = 0, \\ 1 - x - z + 2xz, & y = 1, \\ x + y - 2xy, & z = 0, \\ 1 - x - y + 2xy, & z = 1 \end{cases}, t \in [0, +\infty)$$

$$(14)$$

In such case, the analytical solution has for form below

$$u(t, x, y, z) = x + y + z - 2xy - 2xz - 2yz + 4xyz, \quad (x, y, z) \in \Omega, \ t \in [0, +\infty)$$
(15)

3.3 Discretization

To begin with discretizing the objects or regions we intend to evaluate via matrices, we consider a straightforward approach: using the coordinates in d = 2, 3 dimensional spaces and the function values at those points to simplify the objects. This naive approach works well for investigating objects with regular shapes, such as a cube.

For the FDTD (Finite-Difference Time-Domain) method, we use a finely generated d-cube with shape $\{n_i\}_i^d$. Including the boundary conditions, the cube has $\prod_i (n_i + 2)$ nodes. It requires $4 \prod_i (n_i + 2)$ bytes for float32 or $8 \prod_i (n_i + 2)$ bytes for float64 to store in memory. With this setup, for equally spaced nodes, we have:

$$\Delta x_i = \frac{1}{n_i - 1} \tag{16}$$

Unlike the previously generated regular grid of points with dimensions $n_x n_y n_z$, another strategy is to randomly generate the same number of points based on the same known conditions, covering both the central part and the boundary. In this scenario, shown in figure, there are $n_x n_y n_z$ central points, with function values set according to the boundary conditions, and $2 \times (n_x n_y + n_y n_z + n_z n_x)$ boundary points to be solved. This set of points can be used for training a PINN model.

4 N-DIMENSIONAL MATRIX IMPLEMENTATION

4.1 General Setups

 Initially, we need to determine the data types to be used and define macros for assertions and helper functions to ensure that the program can detect common bugs and report their locations. These features can also be disabled in the release version for performance optimization. Such details are defined in the assert.hpp, helper.hpp, and other related header files located in the subfolder.

4.2 Template Multi-dimension Matrix Detail Design

The FDTD method is a type of FDM. The main idea behind FDM is briefly outlined in Section 2.1. The challenge lies in implementing it in a computer system to ensure it runs both correctly and efficiently. Also, the data types I am using for storing sizes are unit32_t and unit64_t while I used them as Dworld and Qworld respectively, also are defined as size_type and super_size_type in __detail namespace.

4.2.1 Performance Balancing.

Template Class. Instead of doing this by using hierarchy in C++, which will cause the memory of object becomes complicated and unpredictable, and leading to scattered data members between base and derived class objects. This scattering can increase the cache misses which accessing these members, as the data might not be contiguous in memory. Also, with deep inheritance hierarchies, program has higher change to occur diamond problems, since it increases the code complexity. In detail, the diamond problem leads the duplicate inheritance and ambiguity in the method resolution, which will drop performance down again. Although, it is solvable by using virtual inheritance, but again, it increase the complexity.

In such case, I chose to use template class to design the matrix object, which implement compile-time polymorphism as opposed runtime polymorphism provided by inheritance and virtual functions. With such template design, the compiler makes the decisions about which function or class instantiate is made at compile time, eliminating the need for vtables and indirect function calls, which leads to more efficient code.

Memory Management. Rather than using the standard library's (STL) vector module, which can be slower due to the overhead of row pointers, I opted to build the Matrix object using a unique pointer (std::unique_ptr), which includes only basic features such as reset, swap, and most importantly, a destructor that automatically deletes pointers. This approach enhances the safety of memory management in our programs. Additionally, from a safety perspective, given that I implemented many features within the matrix object, I followed standard library conventions for naming. This includes using the __detail namespace within namespace multi_array to hide objects and features that are not intended for direct use by the end user.

4.2.2 Template Object Design of Matrix Shape.

Strides. Besides that, in the multidimensional cases, the size in each dimension is not enough for accessing variables, this is where we need the strides member variable, which stores the number of element the operator needs to skip in each dimension. The __multi_array_shape object is encapsulated within the __detail namespace and serves as a member variable of the later template object for the multi-dimensional matrix. This object includes a member variable defined using the STL vector, as the shape object primarily stores the sizes for each dimension, which typically

requires only a small amount of space. Additionally, this object provides member functions to access the size of a given dimension.

```
Algorithm 1 Stride implementation
```

```
1: dims # STL vector, stores the matrix's size in each dimension.
2: strides # STL vector, has the same size with dims.
3: n = dims.size() # Store the dimension of matrix.
4: strides[d-1] = 1; # Stride is 1 in the first dimension.
5: for d = n - 1; d > 0; -d do
6: strides[d-1] = strides[d] * dims[d] # Determine stride in the latter dimension.
7: end for
8: return strides
```

Performace Balancing. In certain scenarios, we only require the shape information of a matrix without needing to access the entire matrix object. Accessing the shape information through well-defined operators is a more efficient way to handle multidimensional matrices. This is particularly crucial in parallel programming, where understanding the shape of a matrix is of critical importance. Sometimes, a process may need to know the shape of matrices stored on other processes. In such cases, using this matrix object as a local variable within functions increases the likelihood that the compiler will store it in a register, which is generally faster than using heap or stack memory. In addition, it includes check and cast functions that allow the user to verify if the template data type ___T is signed using constexpr. The constexpr keyword ensures that this check occurs at compile time, and if the data type is not legal, the program will assert and provide a message indicating that the indexing value must be a non-negative number.

4.2.3 Template of Multi-dimensional Matrix Implementation. The Matrix in this project is designed to support various data types in C++. Consequently, the matrix is implemented as a template class with several essential features, template variable __T and __NumD, for the value data type and number of dimension, also including iterators, swap functionality, fill operations, and support for the IO stream operator «. To facilitate this, the __array_shape object is used to explicitly manage and access the array's shape information.

Operator (). The hard part of this object designed is the support template number of dimension, whereas the dimension is integer not less than 1, the operator of access element is designed by following algorithm

Algorithm 2 Operator (Ext ... exts) of template matrices object __detail::__array

```
1: __NumD, __T;
2: FINAL_PROJECT_ASSERT_MSE
3: index = 0, i = 1
4: indices[] = __shape.check_and_cast(ext)
5: for i < __NumD; ++i do
6: index += indices[i] * __shape.strides[i]
7: end for
8: FINAL_PROJECT_ASSERT_MSE
9: return __data[index]
# Template variables: dimension, data type.
# Number of Arguments must Match the dimension.
# The indexes number must none-negative number.
# The indexes number must none-negative number.
# The indexes number must none-negative number.
# Boundary checking.
```

Overload operator «. In order to print the multi-dimension array with operator «, I designed a recursive helper function to print the matrix on given dimension. Thus we could call the function on the first dimension, and it will recursively print all dimensions.

                                                                          # Print a newline after each dimension.
18:
19: end if
```

4.3 Template Multi-dimension Matrix Interface Design

With contiguity of safety, this object of multi-dimension array is accessible to users without direct visit to the memory space where store values of matrix.

- 4.3.1 Resource Acquisition Is Initialization (RAII). This private object has only a member variable, a unique pointer to the template __array, and other member function provide necessary features to operating on it. Smart pointers acquire resources in their constructor and automatically release them in their destructor, which is the essence of RAII. By releasing resources in the destructor, smart pointers help prevent resource leaks. When an exception occurs, smart pointers automatically release resources, preventing resource leaks, thus it enhanced the safety level of using resources, reduce the potential memory leak problems.
- 4.3.2 Template Multi-dimension IO for writing to/reading from file. Initially, the multi-dimension matrix has variables shape, and values which given dimension and size in each dimension. This template design end up with these variable can be stored in given data types also leads with lower portability. To avoid such problems and from other point of views, I chose to store the matrices in binary format, rather than other type files. There are couple benefits of doing so,
 - (1) Compatibility and Portability: The format of binary files is relatively stable and can be easily used in different programming environments or applications. Unlike .txt files, .mat files those has less compatibility across different platforms.

(2) I/O Performance: Binary files can perform block-level I/O operations directly without needing to parse text formats or convert data types. This usually makes reading and writing binary files much faster than .txt files, especially when dealing with large-scale multidimensional matrix data.

(3) Support MPI IO: Binary files support the MPI IO, which provides a significant reduction in the cost of communication, when storing and reading the large scale matrices.

However, the IO does not play a critical role in effects performance of FDTD algorithms, if and only if we need to store or load the data during evolving the arrays.

5 PARALLELIZATION OF MULTI-DIMENSIONAL MATRICES ON CARTESIAN TOPOLOGIES

5.1 MPI Parallel Environment Design Scheme

5.1.1 MPI Setups.

Environment. Similar to how malloc in C and new in C++ require manual memory management, the MPI environment also necessitates explicit initialization and finalization. However, unlike the efficient implementation of smart pointers in the STL, Boost.MPI[16] -a high-level parallelism library— may not be the optimal choice for high-performance programs. Therefore, I chose to design a custom MPI environment that encapsulates the necessary features specific to this project.

The mpi namespace, a sub-namespace of final_project, provides the environment class. This class integrates MPI initialization using the constructor, which invokes MPI_Init_thread, provides multi-threading shared memory parallelism in MPI, and MPI finalization through the destructor, which calls MPI_Finalize.

It also offers direct access to the rank and the number of processors within the MPI communicator. Furthermore, I have explicitly deleted the copy and move assignment operators to enhance safety. This design decision aligns with the RAII principle, ensuring that MPI environment resources are automatically managed, thereby preventing leaking and using-uninitialized problems.

Types and Assertions. Aligned meta-programming with polymorphism principles, I designed a template function to retrieve the corresponding MPI basic data types, leveraging the fundamental data types I defined as traits at the outset. Moreover, I provides some MPI macros in assert file, these macros provide a unified interface for dealing with MPI-related errors, ensuring that MPI errors are handling consistently, safely.

5.1.2 MPI Topology (Cartesian). The namespace topology is a sub-namespace of mpi, the template Cartesian structure is the mainly used object in following problems. To optimize memory usage, this object maintains only essential multi-dimension matrices' global and local shape member variables. It also contains a MPI Communicator and MPI value data type, halo data type along with the neighbors' rank in the source and dest sites. To ensure the MPI security, the copy and move constructors as well as assignment operators are manually removed. Additionally, the destructor is customized for properly release halo data type and Cartesian communicator.

Determine the local matrix's localtion. Evenly distributing tasks across processes is of critical importance. To address this, I designed an algorithm to divide an integer N evenly to n clients, where I could put it in use in many cases. Rather than implementing a standalone function, I chose to implement a lambda function, which is a feature in C++ that do not significantly impact the performance. It allows me to design a small function which is not frequently use or play a key role in performance. Ideally, this function will be only called when I construct the MPI topology based multi-dimension M an uscript submitted to M to M to M to M an uscript submitted to M to M to M to M an uscript submitted to M to

# const Integers, total number and current rank of Processor.
 1: n, rank
2: N
                                                                                   # constant Integer, Problem size.
3: s, e
                                                                                       # Integer, start, end indexes.
 4: n_loc = n / N
                                                                                      # Divide the problem evenly.
 5: remain = n % N
                                                                                         # Get the remaining tasks.
 6: s = rank * n_loc + 1
                                                                                      # Calculate the start indexes.
 7: if rank < remain then
                                                           # Give a task to process the rank is smaller than remain.
     s += rank
     ++n_loc
                                                                                     # Update local number of tasks.
10: else
     s += remain
                                                                 # Add the remain to start index, after split remains.
11:
12: end if
                                                                                          # Get the ending indexes
13: e = s + n_{loc} + 1
14: if e > n or rank == N - 1 then
     e = n
                                                                                              # If it is the end of all.
16: end if
```

array, where I need cut the global matrix's shape evenly and create local matrices with local shape. Using local shape to create local matrices is obviously a memory-saving techniques when the problem size gets larger. Eventually, the lambda function is only applied in constructor of template Cartesian structure, which constructed from an input global and a MPI topology environment.

Moreover, the topology information is determined by MPI_Cart_coords for the coordinates and MPI_Cart_shift the neighbors of each process in all dimension. Below is a example [Fig. 4] of cartesian topology of 24 processors, with no period in all dimensions.

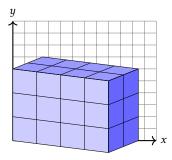

Fig. 4. An example of MPI Cartesian topology Scheme of 24 processors.

Determine MPI datatypes for communication. In order to do MPI communications, the source and the destination of every process are necessary, also the datatype. When working with the meta-designed multidimensional matrix, we need to utilize the function MPI_Type_Create_subarray to create essential halo datatypes.

5.2 Template Distributed Multi-dimension Matrix Design

5.2.1 Detail Object Design. Adhering to the STL safety routines, I chose to create detail template class object, hidden from users, named __array_Cart<class __T, __size_type __NumD>. Here, the __T represents the value type, Manuscript submitted to ACM

```
677
        1: array_size, array_subsize, array_starts={0}
                                                            #std::array<Integer, NumD>, the information of matrix.
678
        2: for i = 0 : NumD do
679
            Split tasks in dimension i by calling decomposition
680
            array_size = local shape
681
            array_subsize = array_size - 2
682
          end for
683
        7: for i=0 : NumD do
684
             temp = array_subsize[i]
                                                                                       # Store the number temporally.
            array_subsize[i] = 1
            MPI_Type_Create_subarray and MPI_Type_commit()
                                                                             # Create halo in dimension i and commit.
       10:
       11:
            Restore temporal array sub-size.
       12: end for
```

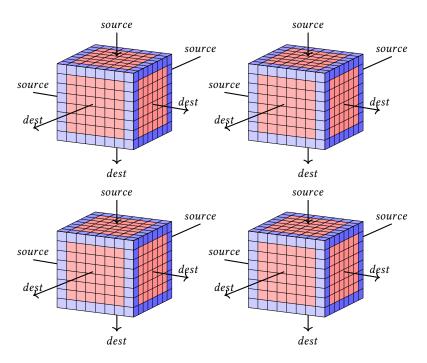

Fig. 5. A 3D MPI Communication Scheme of 8 processors between 3 dimension matrices.

__size_type specifies the type of number of dimensions. Since it is internal and not exposed from users, I decided to directly use other detail objects as member variables rather than smart pointers. In this context, Cartesian matrix has public member variables __array and topology::Cartesian, and provides memory operations. But the copy, move constructors and assignment operators are removed. This approach enhances both performance both performance and simplicity by avoiding unnecessary abstractions in the internal design while maintain a robust memory management.

Distributed operator «. The STL os stream operator « prints the matrices of all processes in sequence which build on multidimensional matrix's. Thus the Unix standard fflush function is utilized for flushing the cache in terminal, to ensure the stdout is print immediately.

Manuscript submitted to ACM

5.2.2 User Interface Design. The array_Cart<class T, size_type NumD> is an object exposed to users, whereas only provides limited access to member variables by smart pointer. As the size of matrices stored, it becomes clear that memory management is critically important. Secondly, especially in MPI distributed matrices, exposing direct memory access by set it to public member is dangerous. With the profits mentioned in Section 4.3.1, using unique pointer brings more benefits in this scenario,

- (1) MPI program memory management has higher complexity level. Adhering RAII routines, the resources are bind with object, including MPI objects, and will be deleted as the object destructed.
- (2) Simplifying Concurrency Control. Synchronization between processes is a critical issue. By using the RAII, user could unsure the resources are locked or released automatically, preventing the risk of deadlocks and resource contention.

5.3 Template Gather of Cartesian Distributed Multi-dimension Matrix

The inverse of distributing multidimensional matrices [Sec. 5.2] based on MPI Topology [Sec. 5.1] is gather all distributed matrices to root from all processes. Unlike operating on ordinary objects, gather function is operating on template objects which makes MPI operations harder. Rather than applying full specialization for each dimension, continuing using meta-programming skills on this brings couple promotions

- (1) Meta-programming, significantly reduce the redundancy of code, where I found the gathering operations on each dimension are highly repeatable.
- (2) Creating MPI Datatype also can be simplified due to the benefits of polymorphism. Especially when handling the high-dimension matrices.
- (3) Using template makes the function is eligible to apply on various value basic data types, Float, Double etc, and provides consistency when handling uncompatible data type.
- (4) Meta-polymorphism is more likely to have better performance, the initializations of template function are completed in compile time, which means there will be no run-time type-checking or type-casting.
- 5.3.1 Implement of Gather. The Gather has following prototype, with the value type of entities of matrices and number of dimension as size_type,

```
template <typename T, size_type NumD>
void Gather(gather, loc, root);
```

Listing 1. Prototypee of final_project::mpi::Gather

where:

- gather is a reference of multi_array::array_base<T, NumD>, which will collect local data and store as the global matrices.
- loc is a constant reference of the local matrices of const array_Cart<T, NumD>, which holds local values
 and will sending data to root process.
- root is a constant Integer, stands for the rank of root process.

The main idea of this function follows the following algorithm

Algorithm 5 Scheme of Gather local matrices to Root process.

                 end if
795
              end for
796
        15: end if
797
```

5.3.2 Determine Local Information. Initially, the matrix object is designed on compatibility, it can read/load data from binary .bin files. Thus the distributed matrices are saving on the root process, by iterating through all processes, calculating the sizes and start indices on each dimension. Receiving them using MPI_Recv from other processes send by MPI_Send.

Considering boundaries, given a D dimensional matrices, with global size $N_{glob} = \{N_{glob}^d + 2\}_{d=0}^{D-1}$. The local matrices has shape $N_{loc} = \{N_{glob}^d + 2\}_{d=0}^{D-1}$, starts from $S = \{s_d\}$ and ends from $E = \{e_d\}$ globally. In the d dimension, as long as the matrix starts s_d equals to 1, it aligns the global boundary from source site which means the index should step back to 0 to include the boundary. In other side, the global boundary locates at the contiguous address in d dimension, the matrix should send a more dice in this dimension, which means the sending size $N_{loc}^d + 1$. Moreover, for the special case when there is only one process.

Adhering the RAII design, Gather function is exposed to user, thus I have not apply swap memory operation between Cartesian distributed matrices and none-distributed matrix just for handling the corner case. Eventually, I solve this by introducing an additional variable called back, which means the Root will copy for layer of data to another matrix. By default, back is 0, and will be set to 1 if and only if the number of process is 1.

With above analysis, the scheme of find local information follows

5.3.3 Creating Send/Recv MPI Datatype. Local MPI communications are low efficient operations comparing to local memory copy operation, memory was used to recursively copy contiguous data from local matrix to global matrix exclusively on root process. In a matrix with undefined dimension, creating data types for communicating is harder than in a specialized matrix. For the none-root processes, they should send their data without ghost values, thus the MPI_Type_create_subarray was used to create a sub-array MPI_Datatype for sending message to root process.

```
826
         MPI_Type_create_subarray(
827
             dimension,
                                        /// Dimension of this array : NumD
828
                                       /// shape of local array
            array_sizes.data(),
                                                                     : local_shape
829
             array_subsizes.data(),
                                       /// shape of sub-array
                                                                     : N_cpy
830
                                       /// starting coordinates
                                                                     : {0, 0, ..., 0}
831
             array_starts.data(),
832
       Manuscript submitted to ACM

                                /// Old MPI Datatype
                                                          : get_mpi_type<T>()
     &sbuf_block);
                                /// New MPI Datatype
```

Listing 2. Routine for creating sub-array MPI_Datatype as send buffer.

The local arrays have shape \mathcal{N}_{loc} , and the sub-arrays have shape $\{N_cpy\}_{d=0}^{D-1}$ determined by above routines [Alg. 6] respectively, the starts indexes are unified as 0s. On the root process, the only difference is that the global shape of array array_sizes are equal to the shape of global matrix.

- 5.3.4 Local Copy Recursive Function. The memcpy can only copy limited data to global matrix once, since the elements we want to gather are not aligning on contiguous memory, but only a small amount of them on the 0 dimension are continuously located. Dut to the dimension of matrix is polymorphic and from the efficiency concern mentioned above [Sec. 5.3.3], the smallest copy operation using memcpy was encapsulated in a lambda function for recursively call and only visible in limited scope.
- 5.3.5 Performace. Gather function is a computationally expensive operation when the scale is large and runs across thousands of processes. With this reason, gathering results is not a optimal choice for getting results in practical. However, the performance balancing is still important since helpful for debugging and stay a health routine of coding. In a brief, I specific designed some performance tunning features for following reasons
 - (1) Using lambda function can slow down the performance, however, gather operation is not always the core of a program since it's an IO operation for debugging or get the final results at the very end. Besides, it's only available when the root process is receiving data, which is a small scope compare to the other parts. In all the drawback can be ignored in this case.
 - (2) The gather matrix is only initialized when we need gather the results. The reason for initializing gather object in this function, is that gather matrix is conventionally very large. If it is create in advance, it will consuming large amount of memory space, which will reduce the rate of memory hit rate, affect the speed of latter computing.

Algorithm 7 copy_recursive(size_type): Copy data using memcpy on given dimension

```
1: Given current dimension dim.
2: if dim == Num - 1 then
    memcpy(
                                                                            # Copy data from local to global.
      gather.begin() + gather.get_flat_index(loc_idx),
                                                                         # Get saving index in global matrix.
                                                                     # Get copy start address of local matrix.
      loc.data() + loc.get_flat_index(loc_idx),
                                                                                     # Number of elements.
     n_list_cpy[dim][pid] * sizeof(T)
    );
4: else
    for i = start_cpy[dim] : loc.ends[dim] + back do
      local_indexes[dim] = 1
                                                                    # Recursive calling, copy next dimension.
      copy_recursive(dim + 1)
    end for
9: end if
```

(3) Adhering RAII routine, I chose to make an copy of each parameters of local and global metrics. While these objects are relatively short, creating them locally could help us make the original data safe, and make them have higher chance stored in register or cache which a lot faster than reading/writing from/to memory.

Building a gather function is indeed convenient, as it allows us to collect data from all processors, and just using IO features of N-Dimension matrix designed previously. However, as discussed in earlier section 5.3.5, even with optimizations on resources usage and MPI performance, the gather function still becomes increasingly inefficient as the problem scale grows. Also, the gather demands more memory space as it requires enough memory on the root processor to store the full-scale final solution. Given that memory is often limited and highly expensive, it is more reasonable to use MPI-IO to implement the parallel I/O, where MPI-IO enables all processes to write results directly to disk. Using MPI-IO offers several significant advantages:

- (1) Significantly reduces the I/O and communication burden on the root processor, as the root no longer needs to gather data from all other processors before performing I/O operations.
- (2) Completely eliminates the overhead associated with the complexity of MPI communication, which previously consumed substantial resources and execution time in the gather function. By using all processors to perform I/O operations directly to disk, this overhead is entirely removed.

From the other perspective, applying MPI-IO will not improve performance of latter FDTD methods or PINNs, but it is a good habit for meta-programming which allows us do debugging work conveniently on larger scale problems.

In order to do this, MPI_Win_set_view will be used. Before that, the file data type (filetype) should be set first to facilitate non-contiguous memory access. I had not chose to use MPI_Type_create_darray, since it is used to generate the data types corresponding to the distribution of an N-dimensional array of oldtype elements onto an N-dimensional grid of logical processes without considering ghost boundaries.

Due to I have determine the start indexes using lambda function [Alg. 4], the MPI_Type_create_subarray was used for creating newtype for creating file views. Displacement was the designed for holding size of N-dimension array, and it is read/write from/to root process. After the file view created, all processes write data into the file associated with file view collectively. Note that the MPI_File_write_all and MPI_File_read_all are collective operations, which means Manuscript submitted to ACM

the function will return only when all processes return. However, the side-effect of such blocking operation is limited for getting final results.

6 PDE SOLVER IMPLEMENTATION

6.1 General Setups

 In general, the building a template solver is no longer a performance-efficient choice, since the optimization of compiler more unpredictable and details across different dimensions are various, especially for latter MPI/SMP hybrid solver implementation. However, for the same PDE, it is quite obvious that there are many commons among different dimensional version. If I design fully isolated objects for each dimension is an expensive idea, which significantly increases the complexity, redundancy and makes the program harder to maintain the consistency. In this scenario, I chose to follow a pattern called template method pattern, which designed a base object, includes a framework of solving this PDE and basic features required. This pattern has many advantages, such as

- (1) Significantly decrease redundancy, complexity of program, the repeated parts are extracted into base objects.
- (2) More flexible for designing features specifically for each derived objects. Makes the programer truly focus on the features designed for each object, with no need for worrying the general features of base object.

6.2 Initial/Boundary Condition Object Design

6.2.1 Initial Condition Class. InitialConditions is the namespace where all initial condition classes located. In the long tern, this it will include initial conditions for heat equation in different dimension space, so as other type of PDEs. For this project, I implemented two classes, Init_2D and Init_3D for 2D and 3D heat equations. Both of the classes have private member std::function objects, that store the function in mathematical form $\varphi(\vec{x})$, such as the equation 12. Default constructors of them are set the $\varphi(\vec{x}) = 0$, once the classes are initialized, the boolean value isSetUpInit will be set to true. Since inits objects are friend of the PDEs objects, user can apply this objects to PDEs objects by calling SetUpInit. The syntax friend brings several benefits

- (1) It will enhance encapsulation, especially in this case, init objects and PDEs object don not need closely work together, exposing internal implementation details to each other would violate the principles of encapsulation.
- (2) Also, it helps keep the class interface clean, only exposing the necessary members while keeping the rest the implementation details hidden.

6.2.2 Boundary Condition Class. Boundary Condition is friend class of PDE classes that located on cube domain, and can be a tedious and hard implementation, due to there are 6 functions in 3D space and 4 in 2D space. Thus, I had not chose to use virtual inheritance pattern on this implementation. Moreover, there are mainly three type of boundary conditions, Dirichlet, Von Neuman and Robin, also known as first, second and third type of boundary conditions.

In this project, I chose to imply first and second type conditions, which denoted with member variable std::array<Bool, 2*NumD> isDirchletBC and std::array<Bool, 2*NumD> isNeumannBC. Similarly to init classes, the SetBC is also a function for apply this boundary condition to PDE objects and the status of setup is stored as a boolean isSetUpBC. However, unlike the initial condition, the Von Neumann boundary conditions need to be update during evolving processes. Thus, an additional member called UpdateBC is designed for handling this case. This member function will update the boundaries which is set as Von Neumann conditions and leave the Dirichlet conditions' alone.

Implementing boundary conditions can be a tough task, since the domain of a problem commonly is commonly not regular shape such as cube or cylinder. Especially the derivatives are required in the Von Neumman and Robin conditions.

6.3 PDE Solver Objects Design

For solving a PDE system, it's necessary to store the parameters of basic this PDE. Take Heat Equation [E.q. 4] as an example, the domain $\Omega = [0, 1]^2$, and coefficient $\lambda = 1$. Besides that, there are extra setups needed for the FDTD methods' iteration, including

- (1) Determine time and space step sizes and other parameters needed from FDTD.
- (2) Exchanging (Communication) between different processors.
 - (a) Using blocking MPI communication methods, MPI_Sendrecv.
 - (b) Using non-blocking MPI communication methods, MPI_Irecv, MPI_Isend.
- (3) Updating (Evolving) function to compute the values of next status in time domain.
 - (a) Purely MPI, no threading updating strategy.
 - (b) Hybrid of MPI/OpenMP, MPI process's has threading.

6.3.1 Abstract Base Class. The default copy/move constructors, copy/move assignment operators of base object are deleted due to it is abstract base class and only provides a unified design. The constructor, member variables and virtual functions are set as protected, which can be accessed by derived classes exclusively.

Constructor. Constructor takes template arguments of extents as inputs, and using extents to determine domain and grid sizes. According to the general setups in section 3.2, and CFL rules, the D dimension heat equation has time step size

$$\Delta t \leqslant \frac{1}{2\lambda \sum_{i=1}^{D} \frac{1}{\Delta x_i^2}} \tag{17}$$

Moreover, I chose to use the modified CFL [8] shown below

$$\Delta t \leqslant \frac{\min_{i=1}^{D} \{\Delta x_i\}^2}{2D\lambda} \leqslant \frac{1}{2\lambda \sum_{i=1}^{D} \frac{1}{\Delta x_i^2}}$$

$$(18)$$

The weights and diagonal coefficients are

$$\begin{cases} w_i = \frac{\lambda \Delta t}{\Delta x_i^2} \\ diag_i = -2 + \frac{\Delta x_i^2}{2\lambda \Delta t} \end{cases}$$
 (19)

Pure virtual functions. Virtual functions overcome the problems with type-field solution, which I used in earlier deprecated versions, it allowing me to declare functions in the base class in advance, and redefined in each derived class. The compiler and linker will guarantee the correct correspondence between objects and the functions applied to them. The type-field solution has several drawbacks:

(1) Using constructs like switch-case and if-else requires frequent modifications to the conditional expressions whenever a new type is added.

(2) The reliance on type casting increases the risk of errors, making the program more prone to runtime issues.

(3) As the number of types increases, the codebase becomes increasingly redundant and difficult to maintain.

The virtual functions in base class stands for

 virtual Exchanging functions mean that the derived class will provide specific definition of different exchange strategies.

• virtual Evolving functions shows the derived classes have 2 different hybrid updating strategies.

6.3.2 PDE solver class. Derived template classes PDE solver objects are Heat_2D<typename T> and Heat_3D<typename T> inherit from Heat_Base<typename T, size_type NumD> with level protected. Each PDE solver class has integrated solver functions, and stands for two types of methods that are pure MPi parallelism [Sec. 6.4.1] and hybrid parallelism. Moreover, the hybrid parallelistic solver has two type of hybrid strategies which I will demonstrate in latter section and section 6.4.2 and 6.4.3.

Safety. The PDE solvers are unified interface objects with integrated IO features, solvers and functions allow to interacting with boundary conditions and initial condition objects, same as previous sections, I chose to use unique pointer to create objects of boundary and initial conditions which adhere RAII protocol. Also, redefining virtual functions of base class using override final phrases that means these functions are not safe for overloading if latter program want to override in second derived classes.

Performance. Every solver class has two objects of Cartesian distributed arrays, the updating strategy I was using is called ping-pong strategy or red-black strategy. This requires us to update values between two objects, one of which store the current status, the other for next status. Obviously, this is a memory-hungary strategy, which requires twice as much as the actual memory space needed for storing local array. However, due to our parallelistic topology, the local arrays are quite smaller than the actual scale of problem, more importantly, it increase the efficiency of updating values in one CPU clockwise.

6.4 Parallel Strategies

The MPI-3.x introduced shared memory programming unlike OpenMP library, Independent Software Vendor (ISV) and application libraries need not to be thread-safe No additional OpenMP overhead and problems. In general, the Parallel Programming Models on Hybrid Platforms have 13 types [18].

In this project, I chose to implement three parallel strategies

- Pure MPI: only one MPI process on each core.
- hybrid MPI + OpenMP with non-overlapped communication/computation: inter-node communication OpenMP: inside of each SMP node, MPI only outside of parallel regions of the numerical application code.
- funneled hybrid + Open with overlapped communication/computation: MPI communication by one or a few threads while other threads are computing.
- 6.4.1 Pure Message Passing Parallel. Pure MPI parallelism is a type of strategy that do not take shared memory programming into considering. With no worry about NUMA structure, pure MPI only needs to determine what is the efficient way for communication, such as

(1) Blocking communication, it is a type of communication with internal barrier, which is only favorable when we need to ensure the latter operations depend on this MPI communication, such as reduction, gather, broadcasting and scattering.

- (2) Non-blocking communication, it is the other type of communication with no barrier. This is advantageous in scenarios where subsequent operations do not depend on the completion of the communication, allowing computation and communication to overlap, which can improve overall efficiency.
- (3) Remote memory access (RMA), the need for explicit send/receive pairs, RMA operation is directly access memory of other CPUs. This can be very efficient, particularly on systems with hardware support like RDMA (Remote Direct Memory Access), However, on systems without such hardware support, RMA may not provide performance benefits and could be slower compared to traditional message-passing methods.

Thus, this projects focused on blocking and non-blocking MPI communications, since RMA requires the hardware support to gain the benefits. In general, Pure MPI strategy follows algorithm The update function update_ping_pong()

Algorithm 8 Pure MPI PDE solver Mechanism

- 1: The i^{th} iteration
- 2: Determine current time of i^{th} step.
- 3: Exchange ghost values.
 - 4: Update, store in the next status.
 - 5: Update boundary conditions at current time.
 - 6: MPI_Allreduce the local difference check if it is converge
 - 7: if No Debug then
 - 8: Store the current results if in Debug mode.
 - 9: Print global difference on root process.
 - 10: **end if**

- 11: Switch current / next arrays.
 - 12: **if** glocal difference ≤ tolerance **then**
 - 13: converge = true, break the iteration.
 - 14: end if

follows the values except ghost values, as the idea of FDM described in equation 6 or more specifically for a D dimension heat equation

$$u_{1,\dots,d,\dots,D}^{n+1} = u_{1,\dots,d,\dots,D}^{n} + \sum_{d=1}^{D} \frac{\lambda \Delta t}{\Delta x_{d}^{2}} \left(u_{1,\dots,d+1,\dots,D}^{n} - 2u_{1,\dots,d,\dots,D}^{n} + u_{1,\dots,d-1,\dots,D}^{n} \right)$$
(20)

Debug mode

The figure 3 shows the evolving scheme of 2D heat equations.

Exchange. Blocking communication is applied with MPI_Sendrecv function which is a unified operation of an MPI_Send to the destination site and an MPI_Recv from source site. The communication topology is shown in figure 5, for each process, there are two MPI_Sendrecv operations, for the destination and source sites communications.

6.4.2 No comm./comp overlapped Hybrid Parallel. The hybrid programming takes shared memory into consider, and the most simple idea is using OpenMP multi-threads for updating arrays of each MPI process.

In the meanwhile, the update function update_ping_pong has a nested loop which is suitable for using parallel for syntax. Thus the update function of the first hybrid strategy is update_ping_ping_omp with OpenMp pragma omp for collapse(NumD). In order to collect differences from all threads of MPI processes, the local difference of threads Manuscript submitted to ACM

are collected to MPI local differences by using pragma omp critical, with a omp barrier at the end. The boundary condition updates and gathering results or print global difference are set to single.

Algorithm 9 Master-only MPI+OpenMP with non-overlapped Communication/Computation

- 1: for iterations do
- 2: #pragma omp single
- 3: MPI communications.
- 4: **for** for grid values **do**
- 5: #pragma omp for updates.
- 6: end for

- 7: #pragma omp single Switch and other operations.
- 8: end for

Exchange. The exchange method of first hybrid solver is identical with pure MPI exchanger, however, only single thread will call it. Such strategy is called Master-Only Hybrid, Page 101 in [18], it can be using omp single for calling MPI communications rather than using omp master. In general the master-only hybrid has such communication scheme

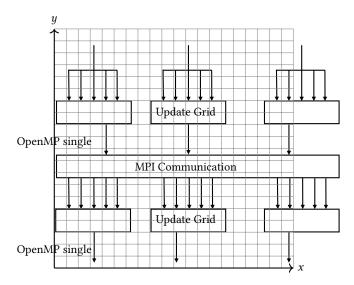

Fig. 6. Scheme: Master only hybrid strategy

6.4.3 Funneled Hybrid Parallel with overlapped comm./comp. Basic on the work in section 6.4.2, the second hybrid strategy is still master-only hybrid but with more optimizations on update function. Due to the inner part of grid is independent with ghost values, thus the update function can be separated the update function into two steps, update the bulk and update the edges.

Comparing to the previous scheme 9, the scheme 10 overlaps part of MPI communications and computation, rather than only take the advantages of shared memory computing.

Algorithm 10 Funneled Master-only MPI+OpenMPI with overlapped Communication/Computation

```
1198
         1: for iterations do
1199
              #pragma omp single
         2:
1200

Wait all MPI Communications complete

Update the points that do not need ghosts.

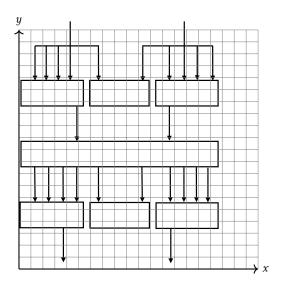

Fig. 7. Scheme: Master only hybrid strategy with computation/communication overlapping

Also, due to the asynchronous communication is not guaranteed by non-blocking MPI communication, which means that the implementation of multiple overlapping of communication / computation. Thus, applying multiple overlapping hybrid method can be very hard to do even on simple question, and highly hardware dependent.

6.5 Physics Informed Neural Networks

The ideas of earlier neural networks mainly focus on multiplying matrices and compute the difference between the outputs and the given labels. AlexNet introduced the convolution product into neural networks since ImageNet Challenge 2014 [15], After that, the type of neurons in networks explosively emerged, including long-short term memory (LSTM) neuron, pooling neural and so on. In the recent years, Maziar, Paris and George [14] brings the differential operators into neural networks, which becomes the Physics Informed Neural Networks (PINN).

In the latter years, many research team combined other type of networks with PINN, such as the transformer operator based PINN [9]. However, many papers were focusing on evaluate the quality of solution which is implemented by Manuscript submitted to ACM

Python or Julia, rather than the speed of training. From the performance perspective, the interpreted programming languages like Pyhon have lower speed comparing to compiling languages such as C/C++. Thus, in this project, I chose to evaluate the training performance on CUDA device implemented by the C/C++ Pytorch library called Libtorch [Libtorch].

- 6.5.1 Dataset. The first part of training a neural network is getting dataset. For the simple purpose, I chose to apply the PINN network for Dirichlet boundary condition which is randomly generate the nodes on boundaries and set the value on that point using boundary condition. This implementation is integrated in to the class dataset under namespace PINN, which can generate training datasets for 2D and 3D heat equation and send the data to a torch::device. Moreover, it can produce a validation grid for showing the outputs of trained network.
- 6.5.2 Structure. The network has the simplest structure, which is a sequential of multiplication of matrices and inputs plus bias (three hidden layers). The activation functions are $tanh(\cdot)$, and the network loss function is mean square error (MSE). Totally, the loss function follows the setting in section 2.2 which is the sumption of $loss_{PDE}$ and $loss_{NN}$ where

$$\begin{cases} loss_{PDE} = \frac{\partial^2 \widehat{u}}{\partial x^2} + \frac{\partial^2 \widehat{u}}{\partial y^2} + \frac{\partial^2 \widehat{u}}{\partial z^2} \\ loss_{NN} = MSE(\widehat{u}, u) \end{cases}$$
 (21)

7 EXPERIMENTS

7.1 Experimental Setup

I verify the proposed PINN methods on generated dataset, and FDTD methods with hybrid and pure MPI strategies on the server with two Intel (R) Xeon (R) Platinum 9242 CPU nodes (96 cores per node) and 4 NUMA nodes per node. While the dataset is using std::m19937 STL random device with given seed 42 [5]. The PINN models I mentioned are trained using train-from-scratch strategy, and maximin number of training times is 1'000'000 epochs. In the setting of learning rate and optimizer, I chose to use Adam with constant learning speed 10⁻³. The details of PDEs are determined in previous section 3.2.

Compiling. Compiling the program is also a critical important processes. I chose to use the macros for defining the scale of problems in advance, this is because the compiler will have more aggressive optimizations if it knows more predefined parameters.

Running. For finely manipulate the resource allocation on cluster, following command line 3 is used for this the script arguments rsc stands for the resource type such as numa, node and socket, -report-bindings is a error message, for showing the details of threads and CPUs tasks allocated on cluster.

mpirun --map-by ppr:\$rpc:\$rsc:pe=\$threads --report-bindings <executable> <arguments>

Listing 3. main command line for launching program on cluster

and threads means the number of threads per resource. The ppr is the number of CPU tasks per resource. The last <argument> is command line arguments for the program, which is designed by programmer. In this case, I designed three type of arguments

- (1) -S, -s Strategy, for specifying the pure mpi, hybrid 0 or 1 strategy.
- (2) -F, -f file name, if this argument is defiend, the results will be stored in the file.
- (3) -H, -h Helper message, the usage information.
- (4) -V, -v Showing the version of program.

7.1.1 Computational Topology. The computational topology is critically important when we are programming parallel PDEs solver softwares. Put the strongly speed-dependent data into the slow memory could make entire program slower.

Cluster. The cluster we are using for this project has 2 sockets per compute node, and each CPU has 24 cores with hyper-threads. The Non-Uniform Memory Access (NUMA) nodes are layout as following Accessing the other NUMA node's memory reduces the bandwidth and also the latency, though the bandwidth is commonly high enough, the latency can increase by 30% to 400% [12]. This latency becomes dangerous when writing shared memory parallel programs.

7.2 Comparison on single node

On single node, the CPUs are connected by high-bandwidth, low-latency internal bus which is faster than connection between nodes. However, for the 4 total NUMA nodes per compute node, memory accessing between them has higher latency than cache. Thus, the first tests set were run on the platform with single node, to evaluate the parallelistic performance of heat equation on 2 and 3 dimension spaces with 3 strategies.

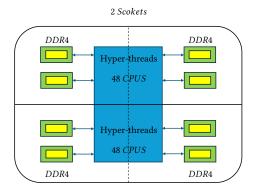

Fig. 8. NUMA topology of single node on Cluster

7.2.1 Strong Scaling. Figure 9 visualizes the comparison of my proposed parallelistic program using pure MPI on two dimension space heat euqation with the number of CPUs and various problem scales. Overall, the more CPUs brings more performance among all scales from 512² to the 32′768² but can not break the speedup limits. Compared with large scale bigger than 4096², the light problems has less speedup as the number of CPUs increases. By seeing the trend of speedup ratios drop as the CPU gets more, the trend can be readily discovered which is the as the scale of problems gets larger, the latter it will have performance-dropping. Once the problem size is large enough, (4096² and larger), the solvers can get the more benefits from more CPUs.

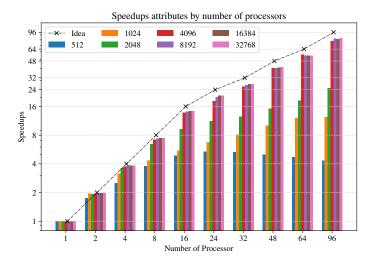

Fig. 9. Comparison of speedup ratios of strong scaling tests of pure MPI parallelized program. The investigated problem scales are the power of 2, exponents ranging from 9 to 15. The number of CPUs are also set as power of 2, with additional numbers 24, 48 and 96 matched the topologies of CPU.

On the other hand, I also include some unconventionaly number of CPUs in scaling tests such as 24, 48 and 96 for comparison, and the results are also shown in the figure 9. From this figure, it is hard to tell the difference of these where it ought to indicate some information about its NUMA structure. This is because the MPI communication does

Manuscript submitted to ACM

 not strongly effected by memory structure, while the hybrid does. Figure 10 shows the difference, the hybrid strategy brings lower performance with small scale across all CPUs and approximately identical in the large scale cases. The most visible change in figure 10(a) is that the speedup ratio of problem with scale 4096² exceeded the limits on 4, 8 and 16 CPUs which is 1, 2, 4 threads of each MPI process. We can also see that when the number of threads is 8 and 4 MPI processes, the performances on large scale is better than pure MPI parallelism.

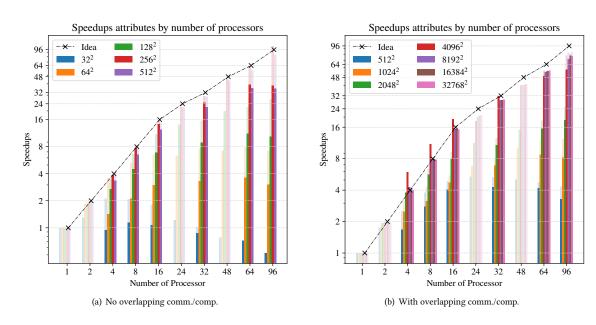

Fig. 10. Comparison of speedup ratios of strong scaling tests of mater-only parallelized program with overlapping and no overlapping of computation and communication. The vague background is the results of pure MPI parallelization from figure 9 and problems sclaes are identical as well. The number of threads are set to 1, 2, 4, 8, 16, and 24, tasks per CPU are 1, 2 and 4.

For the other funneled hybrid parallelization, the figure 10(b) in the appendix shows the details of results, this strategy has nearly idential performance of master only with no overlapping on large problem scales. However, the behaviour of it on small scales has a different pattern. This indicates that the overlappings of computation and communication are not as good as previous one, which means the overload management is not well on these tests.

Superliner Speedup. Conventionally, the actuall speedup won't excedes the theoratical predictions of Amdalh's law. However, the scaling of two hybrid programs did exceded the limits but exclusively on the problem scale 4096² and 1 to 8 threads of each 4 MPI processes. Considering the details of the CPU used for these tests,

- It has 4 NUMA node per CPU and once of which has 12 CPUs with 2 threads.
- It has 32KB L1 data and L1 instruction cache, 1024KB L2 cache and 36608KB L3 cache.

The data type for this solver is Double which takes 8 bytes, and 4096^2 Double numbers takes 128 MB to store. In the case of 4 MPI processes, each process own a quater of number which uses 32 MB for handling sub-problems. On the other hand, the L3 cache is 36608 KB = 35.75 MB which is just bigger than the sub-problem scale 32 MB. When the problem size gets larger, such as 8096^2 which takes 128 MB to store the sub-problem. In such case, the L3 case is no longer able to hold it, thus part of the numbers will be stored in the DDR4 memories which is lower bandwidth and higher latency Manuscript submitted to ACM

Table 1. Weak Scaling on Single Node of 2D Heat Equation

Strategy	Size	Number of CPUs			£ (m)
		4	16	64	$f_{p}(\%)$
Pure MPI		4.006	12.497	47.849	75.1
No Overlap	512^{2}	2.876	11.206	42.754	67.0
With Overlap		3.173	10.818	42.282	66.2
Pure MPI		3.838	9.304	33.707	53.2
No Overlap	1024^{2}	3.947	12.995	33.447	54.1
With Overlap		4.024	12.932	33.361	54.0
Pure MPI		2.376	8.245	31.203	49.0
No Overlap	2048^{2}	3.874	8.972	31.510	49.8
With Overlap		3.740	8.989	31.430	49.7
Pure MPI		3.543	8.245	31.203	77.5
No Overlap	4096^{2}	3.953	13.799	49.515	78.0
With Overlap		3.948	13.800	49.989	78.7

than cache. Moreover, due to the CPU enables hyper-threading, a NUMA node actually holds 12 CPUs, which makes the superlinear speedup disappear when the threads is 16 and 24.

7.2.2 Weak Scaling. Table 1 lists the weak scaling comparison of three different parallel strategies. Overall, both three strategies have good weak scaling results across all problem sizes. For example, according to the Gaustafsson's Law 2.2, the program using overlapped strategy has sequential fraction

$$f_s = \frac{49.989 - 64}{1 - 63} \approx 0.222$$

on the problem scale 4096^2 with 64 CPUs and $f_s \approx 0.147$ with 16 CPUs. For the small size problems, like 512^2 , the pure MPI has significantly higher weak scaling efficiency comparing to the other two, more specifically about 7.8%, 7.5% higher in 64, 16 CPUs, and 22.5% higher in 4 CPUs. However, as the scale gets larger, this advantages gradually disappear and even worse than other two. Especially when 40962 on 16 and 64 cores, the forward leap of hybrid versions gets larger, about 34.4% and 28.1% higher than pure MPI respectively.

On the other hand, the superlinear speedup appears for the problem size with 512² and 1024² on 4 CPUs. This is because the sub-problem for each CPUs only take 512 KB and 1024 KB to store, which is the L2 cache size of the Xeon Platinum 9242. Thus the four processes could take the performance advantages of L2 cache individual for each CPU. Once the problem size gets larger, such as 2048², part of the problem will be allocated on L2 cache and other parts on L3 cache. These memory allocations requires extra synchronization between cache accessing, which drop the performance down. However, as the size gets to 4096², the sub-problem will be fully make use of L3 cache, which require less synchronization of cache, the weak scaling goes up but we can not see the superlinear speedup again.

Moreover, since Gaustafsson' theorem 2.2 gives us a linear module for valuating the parallel problem. Thus I chose to use the linear model from equation 8 as a linear polymonimal fitting. Considering the original point has to be on the line, which stantds for $f_S + f_D = 1$, I manually create an extended version of speedups by concatenate a inverse negative one to ensure their means are 0 which makes the fitting line across the (0,0). Eventually, the results of f_p are shown in the table 1 as well. These fitting lines also indicate that the hybrid parallelized versions has more parallel fraction than pure MPI when the scale of problem gets larger than 512, which means that hybrid strategies reduced the cost of synchronization and brought higher efficiency.

7.3 Comparison on multi-node

 Running programs on multi-node also utilized the command line 3 to specify the resource allocation on cluster. In this setup, I ran the tests on 4 nodes with total 16 NUMA nodes or 384 CPUs, all other settings are maintained from the single-node tests.

7.3.1 Strong Scaling. Figure 11 demonstrates speedup ratio of all candidates for test and their relationships with the number of CPUs. In the big picture, it is easy to determine that the small scale problems (smaller than 4096²) had pool speedup performances on these settings. Especially for the 512², 1024² and 2048², parallelization even brought worse performance in the end, which is strongly different from the big scales. In the large scale problems, the most large two maintained good strong scaling performances at the end, but the pure MPI failed on launching the program when using 384 processes. Moeover, the problem with 4096² numbers show superlinear speedup on 4, 8 and 16 processes which is similar to single-node hybrid tests. However, unlike gaining benefits from shared memory operations on single NUMA node, these superlinear speedup came from the node structure. Where the pure MPI processes were allocated on four different CPU, which has individual CPU clock cycle. Thus, the processes can behave like operating on shraed memory model. In addition, the patterns of the strong scaling are different from the Amdalh'S law 2.1 demonstrates. Which has

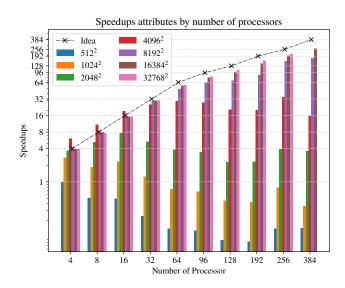

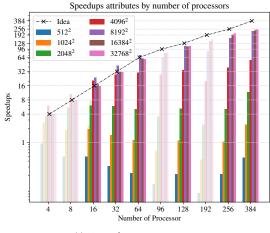

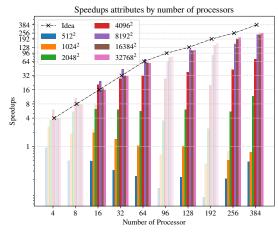

Fig. 11. Comparison of speedup ratios of strong scaling tests of pure MPI parallelized program. The investigated problem scales are the power of 2, exponents ranging from 9 to 15. The number of CPUs are also set as power of 2, with additional numbers 96, 192 and 384 matched the topologies of CPU.

may visible exceptional performance decreases, due to the topologies of CPUs, especially when using 32, 48 and 96 CPUs per node.

On the other hand, based on comparison of the strong scaling speedup ratios and the amount of resources, two hybrid versions performed better than pure MPI parallel and the results are shown in the figure 12. From the figure 12(a) and 12(b), we could see that the superlinear speedup appears on the scale 4096² and 8019² which are effected by the previously mentioned two reasons, the high performance local NUMA node shared memory and individual CPU Manuscript submitted to ACM

clock cycle. More specifically, 8092^2 Double numbers takes 512 MB to store, 128 MB on each node and 32 MB per NUMA node, which just fits the L3 cache size.

(a) No overlapping comm./comp.

(b) With overlapping comm./comp.

Fig. 12. Comparison of speedup ratios of strong scaling tests on 4 nodes of mater-only parallelized program with overlapping and no overlapping of computation and communication. The vague background is the results of pure MPI parallelization from figure 11 and problems sclaes are identical as well. The number of threads are set to 1, 2, 4, 8, 16, and 24, tasks per CPU are 1, 2 and 4.

As the amount of resources increase, the speedups are not increase as expected for all three parallel models. However, hybrid parallel models were successfully launched on the 384 CPUs, and also brought more performance for all tested number of CPUs. These shows that the advantages of combination of shared memory programming and message-passing programming.

7.3.2 Weak Scaling. Table 2 lists the weak scaling comparison results of multi-node tests. Overall, the hybrid models have better scaling speedup ratios than pure MPI model on the size larger than 512². Although the speedups of pure MPI model are better than hybrid models on 16 CPUs with 2048² problem size, the hybrid model with no comm./comp. overlapping still have better performance when testing is running on 64 and 256 CPUs. Controversially, the hybrid with no overlapping has better results comparing to the one with overlapping, and we have opposite results when the scale gets larger.

On the other hand, similar to previous section 7.2.2, the fraction of parallelizable is approximated by linder regression based on the model proposed in theorem 2.2. As the table 2 lists results, the fraction of parallelizable increases as the size gets larger. Moreover, the overlapping has the most large fraction then the model with no overlapping, and both of then are significantly larger than pure MPI model.

There are some important performance leap forward due to the memory structure mentioned in previous section 7.2.2, the L3 cache for single NUMA node just fits the problem with 2048² Double numbers.

• The first one is the number of CPUs increases from 16 to 64, in the case of the problem size is 1024² running on hybrid models, the problem scale of each NUMA node increases from 1024² to 2048² which makes the program requires less cache synchronization and brings about 52.6% more scaling speedup performance.

Table 2. Weak Scaling on Multi-node of 2D Heat Equation

Strategy	Size	Number of CPUs				£ (m)
		4	16	64	256	$f_p(\%)$
Pure MPI		3.300	10.379	26.000	124.375	48.2
No Overlap	512^{2}	-	8.094	25.931	127.648	49.3
With Overlap		-	8.386	27.126	116.951	45.5
Pure MPI		3.848	13.037	30.143	-	49.3
No Overlap	1024^{2}	-	13.702	44.040	-	69.8
With Overlap		-	13.834	44.090	-	69.9
Pure MPI		3.787	9.172	32.013	-	50.6
No Overlap	2048^{2}	-	13.936	34.368	-	55.7
With Overlap		-	14.274	34.414	-	55.9
Pure MPI		3.884	13.859	51.041	-	80.2
No Overlap	4096^{2}	-	15.315	53.157	-	83.8
With Overlap		-	15.294	53.401	-	84.2

• The second is the size of problems increas from 1024² to 2048² when the number of CPUs is 16. With such doubled size, the program can make more use of L3 cache on single NUMA node and brings about speedup 46.6% improvements.

Both of the improvements are about 50%, these results indicates that the hybrid strategies I was implementing are effective, also, the overlapping of computation and communication promoted the speedup further.

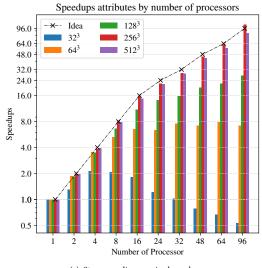

7.4 Comparison on Dimension

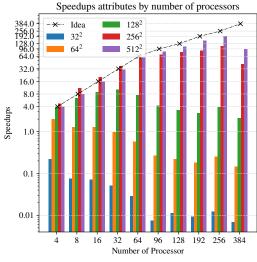

7.4.1 Strong Scaling. The figures 13 show the results of solving 3D heat equation with Dirichlet boundary conditions specified by euqations 14. Conventionally, solving a 3D problem is extreamly computational expensive comparing to solve a 2D problem and hard to be parallelized. Overall, both of them have great strong sclaing speedups in a reasonable problem size and amount of resources. However, considering the size of the problems are common cube of number which is smaller than 1024, we can barely get solution with fine quality in 3D dimension case.

On the other hand, I specify the maximun scale of problem is 512^3 rather than 1024^3 . This is because the pattern of accessing memories is $O(n^3)$ space complexity which leads more time consumption per epoch, although the problem has identical scale $1024^3 = 32768^2$. It also makes us harder to see a large superlinear speedup occurs comparing to 2D problems. In this scenario, only the figure 13(b) shows that the problem with scale 256^3 has superlinear speedup on 8, 16 and 32 CPUs due to the separated nodes has dependent CPU clock whic increase the rate of hitting cache.

The figure 14 shows the details of hybrid parallel models on single and four nodes. Overall, the figures 14(a) and 14(b) show that both hybrid model have worse performance on single node. Even with the benefits of caching, the 256³ scale problem still a little bit loss on speedup on 4, 8 and 16 CPUs. However the figures 14(c) and 14(b) shows completely different results. On the multi-nodes test, overall, all hybrid models have better performance comparing to pure MPI parallelization. Especially for the largest problem 512³ which the pure MPI scaling speedup ratio is 96 under 384 CPUs, the hybrid models gained approximately 130 and 140 speedups which is about 30% 40% improvements. Moreover, the problem with 256³ scale investigated on 8 16 and 32 CPUs reached superlinear speedup at the end, which were making use of L3 cache and asynchronized CPU clock cycle.

As for the promotion gets from the cache and CPU asynchronization, we can discovered that the 2D problems got less benefits while the 3D problems got bigger. This is the 3D problem relys more on the memory accessing, and the shared memory parallelization can do optimizations better than MPI.

(a) Strong scaling on single node (b) Strong scaling on four node

Fig. 13. Comparison of speedup ratios of strong scaling tests pure MPI models on 4 nodes of and 1 node. The problem sizes are set to 32³, 64³, 128³, 256³ and 512³ and data type is Double.

7.4.2 Weak Scaling. The weak scaling results of 3 dimension problems are listed in the table 3. For the single node scaling speedups, we could see that the pure MPI model has better performance over all problem scales and amount of resources. However, for the multi-node tests, the hybrid models have approximately same or better performance than pue MPI model. Especially for the non-overlapped hybrid model.

Table 3. Weak Scaling of 3D Heat Equation

Strategy	Size	Number of CPUs			£ (m)	$\mathcal{L}(\alpha)$
		8	64	$64_{Multi-node}$	$f_{p}(\%)$	$f_p(\%)$ Multi-node
Pure MPI		5.243	26.405	9.078	41.6	14.2
No Overlap	32^{3}	2.124	13.386	8.094	21.0	12.7
With Overlap		2.014	13.884	9.586	21.8	39.7
Pure MPI		7.937	32.034	30.106	50.8	47.1
No Overlap	64^{3}	5.393	20.007	33.460	31.8	52.3
With Overlap		5.200	19.558	35.254	31.1	31.6
Pure MPI		3.513	24.239	25.428	38.0	39.7
No Overlap	128^{3}	3.303	15.235	35.254	24.1	55.1
With Overlap		3.187	15.107	20.096	23.9	31.4

On the other hand, comparing the results from 2 dimension versions shown in table 1 and 2. It is readily to determine that the weak scaling speedup of 3 dimension problems are worse than 2 dimensions. Which means that the fraction of parallelizable parts in 3D problems are significantly lower than 2D version.

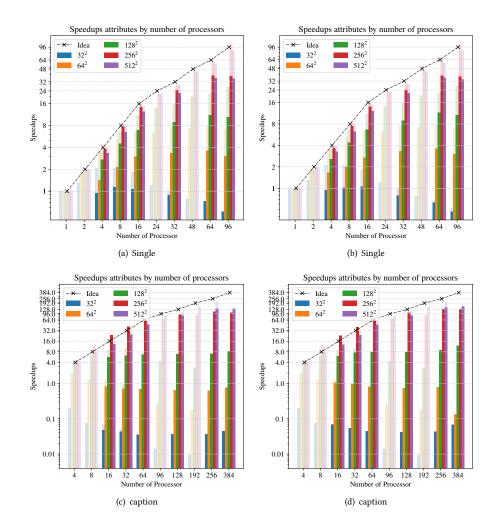

Fig. 14. <caption>

7.5 Comparison on Accuracy, with PINN

 Scalability is important for parallel computing to be effective, so as the quality of results. In this section, the major comparison are about comparing the quality of numerical solutions of 2D, 3D FDTD solvers and a state-of-art method PINN.

7.5.1 Accuracy. When we tried to represent numbers using arithmetic in binary, decimal or hexadecimal, truncation always affects the precision of every number, or so called as round-off-error.

Round-off Error. In IEEE-754 [13] standards, a 32-bit floating pointer number, single precision, obligatorily represented with 23-bit mantissa, 8-bit exponent and 1-bit for sign. Where as 64-bit floating number, double precision, also ubiquitous used, which has 11-bit exponent and 52-bit mantissa. After almost three decades development, not only single and Manuscript submitted to ACM

double precisions (float32, float64) are ubiquitously in use, also more formats such as fp4, fp8, and fp16 etc. Both of them follows the simple form of exponent k, sign n and mantissa N. [13]

$$2^{k+1-N}n$$

Round-off errors are a manifestation of the fact that on a digital computer, which is unavoidable in numerical computations. In such case, the precision of the number depends on how many bytes are used to store single number. For instance, a float32 number provides $2^{-23} \approx 1.2 \times 10^{-7}$, and a double precision number gives $2^{-53} \approx 2.2 \times 10^{-16}$, such number is called machine ϵ which is the smallest number the machine can represent with given format.

In numerical methods I investigated, the FDTDs are conventionally using double precision number so that the programs can treat extreamly large and small numbers simultaneously in the same computation, without worring about the round-off errors. However, as mentioned, fp32 and fp16 are also popular use in scientific computing, especially in machine learning training process. While the lasted training GPUs are integrated compute accelarate unit for low precision floating numbers. [4].

Floating-point Arithmetic. The other type loss comes from the arithmetic operations on two numbers x, y. The standard model holds that

$$fl(x \text{ op } y) = (x \text{ op } y)(1+\delta), \quad |\delta| < \epsilon$$
 (22)

where the *op* stands for the four elementary operations: +, -, \times , /. [6].
